# Describing Chemical Reactions

#### **Key Terms**

chemical equation precipitate coefficient word equation formula equation reversible reaction

A *chemical reaction* is the process by which one or more substances are changed into one or more different substances. In any chemical reaction, the original substances are known as the *reactants* and the resulting substances are known as the *products*. According to the law of conservation of mass, the total mass of reactants must equal the total mass of *products* for any given chemical reaction.

Chemical reactions are described by chemical equations. A chemical equation represents, with symbols and formulas, the identities and relative molecular or molar amounts of the reactants and products in a chemical reaction. For example, the following chemical equation shows that the reactant ammonium dichromate yields the products nitrogen, chromium(III) oxide, and water.

$$(\mathsf{NH}_4)_2 \mathsf{Cr}_2 \mathsf{O}_7(\mathbf{s}) \longrightarrow \mathsf{N}_2(\mathbf{g}) + \mathsf{Cr}_2 \mathsf{O}_3(\mathbf{s}) + 4\mathsf{H}_2 \mathsf{O}(\mathbf{g})$$

This strongly exothermic reaction is shown in Figure 1.1.

#### MAIN IDEA Chemical reactions have physical indicators.

To know for certain that a chemical reaction has taken place requires evidence that one or more substances have undergone a change in identity. Absolute proof of such a change can be provided only by chemical analysis of the products. However, certain easily observed changes usually indicate that a chemical reaction has occurred.

- 1. Evolution of energy as heat and light. A change in matter that releases energy as both heat and light is strong evidence that a chemical reaction has taken place. For example, you can see in Figure 1.1 that the decomposition of ammonium dichromate is accompanied by the evolution of energy as heat and light. And you can see evidence that a chemical reaction occurs between natural gas and oxygen if you burn gas for cooking in your house. Some reactions involve only heat or only light. But heat or light by itself is not necessarily a sign of chemical change, because many physical changes also involve either heat or light. However, heat and light are very strong indicators of a chemical change and should encourage you to investigate further.
- **2.** *Color change*. A change in color is often an indication of a chemical reaction. Again, color change should not be the only physical indicator considered, because color changes can also be physical changes.

#### **SECTION 1**

#### Main Ideas

Chemical reactions have physical indicators.
 Chemical equations must satisfy the law of conservation of mass.
 Chemical equations show relative amounts, masses, and progression of chemical reactions.
 Chemical equations can be balanced with step-by-step inspection.
 VIRGINIA STANDARDS

**CH.3.b** The student will investigate and understand how conservation of energy and matter is expressed in chemical formulas and balanced equations. Key concepts include: balancing chemical equations. **CH.3.EKS-4** 

#### FIGURE 1.1

**Evolution of Energy as Heat and Light** The decomposition of ammonium dichromate proceeds rapidly, releasing energy as light and heat.

**Evidence of Reaction** As shown in the photos, the production of a gas and the formation of a precipitate are two strong indicators that a chemical reaction has occurred.

(a) The reaction of vinegar and baking soda is evidenced by the production of bubbles of carbon dioxide gas.

(b) When water solutions of ammonium sulfide and cadmium nitrate are combined, the yellow precipitate cadmium sulfide forms.

- **3.** *Production of a gas.* The evolution of gas bubbles when two substances are mixed is often evidence of a chemical reaction. For example, bubbles of carbon dioxide gas form immediately when baking soda is mixed with vinegar, as shown in **Figure 1.2a**.
- 4. Formation of a precipitate. Many chemical reactions take place between substances that are dissolved in liquids. If a solid appears after two solutions are mixed, a reaction has likely occurred. A solid that is produced as a result of a chemical reaction in solution and that separates from the solution is known as a precipitate. A precipitate-forming reaction is shown in Figure 1.2b.

#### MAIN IDEA Chemical equations must satisfy the law of conservation of mass.

A properly written chemical equation can summarize any chemical change. The following requirements will aid you in writing and reading chemical equations correctly.

- 1. *The equation must represent known facts*. All reactants and products must be identified, either through chemical analysis in the laboratory or from sources that give the results of experiments.
- 2. The equation must contain the correct formulas for the reactants and products. Remember what you've learned about symbols and formulas. Knowledge of the common oxidation states of the elements and of methods of writing formulas will enable you to write formulas for reactants and products if they are unavailable. Some elements are represented simply by their atomic symbols when they are in their elemental state. For example, iron is represented as Fe and carbon is represented as C. The symbols are not given any subscripts because the elements do not form definite molecular structures. Two exceptions are sulfur, which is usually written S<sub>8</sub>, and phosphorus, which is usually written P<sub>4</sub>. In these cases, the formulas reflect each element's unique atomic arrangement in its natural state.

#### FIGURE 1.3

#### **ELEMENTS THAT NORMALLY EXIST AS DIATOMIC MOLECULES**

Element	Symbol	Molecular formula	Physical state at room temperature
Hydrogen	Н	H <sub>2</sub>	gas
Nitrogen	Ν	N <sub>2</sub>	gas
Oxygen	0	02	gas
Fluorine	F	F <sub>2</sub>	gas
Chlorine	CI	Cl <sub>2</sub>	gas
Bromine	Br	Br <sub>2</sub>	liquid
lodine	I	I <sub>2</sub>	solid

Also remember some elements, listed in **Figure 1.3**, exist primarily as diatomic molecules, such as  $H_2$  and  $O_2$ . Each of these elements is represented in an equation by its molecular formula.

3. The law of conservation of mass must be satisfied. Atoms are neither created nor destroyed in ordinary chemical reactions. Thus, the same number of atoms of each element must appear on each side of a correct chemical equation. To balance numbers of atoms, add coefficients where necessary. A coefficient is a small whole number that appears in front of a formula in a chemical equation. Placing a coefficient in front of a formula specifies the relative number of moles of the substance. If no coefficient is written, it's assumed to be 1.

#### Writing Word Equations

The first step in writing a chemical equation is to identify the facts to be represented. It is often helpful to write a word equation, an equation in which the reactants and products in a chemical reaction are represented by words. A word equation has only qualitative (descriptive) meaning. It does not give the whole story because it does not give the quantities of reactants used or products formed.

Consider the reaction of methane, the principal component of natural gas, with oxygen. When methane burns in air, it combines with oxygen to produce carbon dioxide and water vapor. In the reaction, methane and oxygen are the reactants. Carbon dioxide and water are the products. The word equation for the reaction is written as follows:

methane + oxygen  $\longrightarrow$  carbon dioxide + water

The arrow,  $\longrightarrow$ , is read as *react to yield* or *yield* (also *produce* or *form*). So the equation above is read, "methane and oxygen react to yield carbon dioxide and water," or simply, "methane and oxygen yield carbon dioxide and water."

#### Writing Formula Equations

The next step in writing a correct chemical equation is to replace the names of the reactants and products with appropriate symbols and formulas. Methane is a molecular compound composed of one carbon atom and four hydrogen atoms. Its chemical formula is  $CH_4$ . Recall that oxygen exists in nature as diatomic molecules; it is therefore represented as  $O_2$ . The correct formulas for carbon dioxide and water are  $CO_2$  and  $H_2O$ , respectively.

A formula equation represents the reactants and products of a chemical reaction by their symbols or formulas. The formula equation for the reaction of methane and oxygen is written as follows:

$$CH_4(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(g) \text{ (not balanced)}$$

The *g* in parentheses after each formula indicates that the corresponding substance is in the gaseous state. Like a word equation, a formula equation is a qualitative statement. It gives no information about the amounts of reactants or products.

#### Writing Balanced Equations

A formula equation meets two of the three requirements for a correct chemical equation. It represents the facts and shows the correct symbols and formulas for the reactants and products. To complete the process of writing a correct equation, the law of conservation of mass must be taken into account. The relative amounts of reactants and products represented in the equation must be adjusted so that the numbers and types of atoms are the same on both sides of the equation. This process is called *balancing an equation* and is carried out by inserting coefficients. Once it is balanced, a formula equation is a correctly written chemical equation.

Look again at the formula equation for the reaction of methane and oxygen.

$$CH_4(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$$
 (not balanced)

To balance the equation, begin by counting atoms of elements that are combined with atoms of other elements and that appear only once on each side of the equation. In this case, we could begin by counting either carbon or hydrogen atoms. Usually, the elements hydrogen and oxygen are balanced only after balancing all other elements in an equation. (You will read more about the rules of balancing equations later in the chapter.) Thus, we begin by counting carbon atoms.

Inspecting the formula equation reveals that there is one carbon atom on each side of the arrow. Therefore, carbon is already balanced in the equation. Counting hydrogen atoms reveals that there are four hydrogen atoms in the reactants but only two in the products. Two additional hydrogen atoms are needed on the right side of the equation. They can be added by placing the coefficient 2 in front of the chemical formula  $H_2O$ .

 $CH_4(g) + O_2(g) \longrightarrow CO_2(g) + 2H_2O(g)$  (partially balanced)

A coefficient multiplies the number of atoms of each element indicated in a chemical formula. Thus,  $2H_2O$  represents *four* H atoms and *two* O atoms. To add two more hydrogen atoms to the right side of the equation, one may be tempted to change the subscript in the formula of water so that  $H_2O$  becomes  $H_4O$ . However, this would be a mistake because changing the subscripts of a chemical formula changes the *identity* of the compound.  $H_4O$  is not a product in the combustion of methane. In fact, there is no such compound. One must use only coefficients to change the relative number of atoms in a chemical equation because coefficients change the numbers of atoms without changing the identities of the reactants or products.

Now consider the number of oxygen atoms. There are four oxygen atoms on the right side of the arrow in the partially balanced equation. Yet there are only two oxygen atoms on the left side of the arrow. One can increase the number of oxygen atoms on the left side to four by placing the coefficient 2 in front of the molecular formula for oxygen. This results in a correct chemical equation, or *balanced formula equation*, for the burning of methane in oxygen.

 $CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(g)$ 

This reaction is further illustrated in **Figure 1.4.** As you study the molecular models, consider carefully the effects associated with changing the subscripts in formulas and those associated with changing coefficients. Also, be patient. Balancing equations is a skill that takes practice, and any chemist will admit to it being sometimes extremely complex.

#### FIGURE 1.4

#### **Chemical Equations**

(a) In a Bunsen burner, methane combines with oxygen in the air to form carbon dioxide and water vapor. (b) The reaction is represented by both a molecular model and a balanced equation. Each shows that the number of atoms of each element in the reactants equals the number of atoms of each element in the products.

CHECK FOR UNDERSTANDING Discuss Why are formula equations, using symbols and numbers, used more commonly in chemistry than word equations?

#### FIGURE 1.5

	SYMBOLS USED IN CHEMICAL EQUATIONS
Symbol	Explanation
$\longrightarrow$	"Yields"; indicates result of reaction
	Used in place of a single arrow to indicate a reversible reaction
(S)	A reactant or product in the solid state; also used to indicate a precipitate
Ļ	Alternative to $(s)$ , but used only to indicate a precipitate
(/)	A reactant or product in the liquid state
( <i>aq</i> )	A reactant or product in an aqueous solution (dissolved in water)
( <i>g</i> )	A reactant or product in the gaseous state
Î	Alternative to $(g)$ , but used only to indicate a gaseous product
$\xrightarrow{\Delta}$ or $\xrightarrow{\text{heat}}$	Reactants are heated
$\xrightarrow{2 \text{ atm}}$	Pressure at which reaction is carried out, in this case 2 atm
Pressure	Pressure at which reaction is carried out exceeds normal atmospheric pressure
°C →	Temperature at which reaction is carried out, in this case 0°C
− Mn0 <sub>2</sub> →	Formula of catalyst, in this case manganese dioxide, used to alter the rate of the reaction

#### **Additional Symbols Used in Chemical Equations**

**Figure 1.5** above summarizes the symbols commonly used in chemical equations. As you can see, some things can be shown in different ways. For example, sometimes a gaseous product is indicated by an arrow pointing upward,  $\uparrow$ , instead of (g). A downward arrow,  $\downarrow$ , is often used to show the formation of a precipitate during a reaction in solution.

The conditions under which a reaction takes place are often indicated by placing information above or below the reaction arrow. The word *heat*, which is symbolized by a Greek capital delta ( $\Delta$ ), indicates that the reactants must be heated. The specific temperature at which a reaction occurs may also be written over the arrow. For some reactions, it is important to specify the pressure at which the reaction occurs or to specify that the pressure must be above normal. Many reactions are speeded up and can take place at lower temperatures in the presence of a *catalyst*. A catalyst is a substance that changes the rate of a chemical reaction but can be recovered unchanged. To show that a catalyst is present, the formula for the catalyst or the word *catalyst* is written over the reaction arrow. In many reactions, as soon as the products begin to form, they immediately begin to react with each other and re-form the reactants. In other words, the reverse reaction also occurs. The reverse reaction may occur to a greater or lesser degree than the original reaction, depending on the specific reaction and the conditions. A reversible reaction is a chemical reaction in which the products re-form the original reactants. The reversibility of a reaction is indicated by writing two arrows pointing in opposite directions. For example, the reversible reaction between iron and water vapor is written as follows:

$$3Fe(s) + 4H_2O(g) \Longrightarrow Fe_3O_4(s) + 4H_2(g)$$

With an understanding of all the symbols and formulas used, it is possible to translate a chemical equation into a sentence. Consider the following equation:

 $2 \text{HgO}(s) \xrightarrow{\Delta} 2 \text{Hg}(l) + O_2(g)$ 

Translated into a sentence, this equation reads, "When heated, solid mercury(II) oxide yields liquid mercury and gaseous oxygen."

It is also possible to write a chemical equation from a sentence describing a reaction. Consider the sentence, "Under pressure and in the presence of a platinum catalyst, gaseous ethene and hydrogen form gaseous ethane." This sentence can be translated into the following equation:

$$C_2H_4(g) + H_2(g) \xrightarrow{\text{pressure, Pt}} C_2H_6(g)$$

Throughout this chapter we will often include the symbols for physical states (*s*, *l*, *g*, and *aq*) in balanced formula equations. You should be able to interpret these symbols when they are used and to supply them when the necessary information is available.

#### Writing Word, Formula, and Balanced Chemical Equations

**Sample Problem A** Write word and formula equations for the chemical reaction that occurs when solid sodium oxide is added to water at room temperature and forms sodium hydroxide (dissolved in the water). Include symbols for physical states in the formula equation. Then balance the formula equation to give a balanced chemical equation.

#### SOLVE

The word equation must show the reactants, sodium oxide and water, to the left of the arrow. The product, sodium hydroxide, must appear to the right of the arrow.

#### sodium oxide + water $\longrightarrow$ sodium hydroxide

The word equation is converted to a formula equation by replacing the name of each compound with the appropriate chemical formula. To do this requires knowing that sodium has an oxidation state of +1, that oxygen usually has an oxidation state of -2, and that a hydroxide ion has a charge of 1-.

#### $Na_2O + H_2O \longrightarrow NaOH (not balanced)$

Adding symbols for the physical states of the reactants and products and the coefficient 2 in front of NaOH produces a balanced chemical equation.

 $Na_2O(s) + H_2O(l) \longrightarrow 2NaOH(aq)$ 

Writing Word, Formula, and Balanced Chemical Equations				
<b>Sample Problem B</b> Translate the following chemical equation into a sentence:				
$BaCl_2(aq) + Na_2CrO_4(aq) \longrightarrow BaCrO_4(s) + 2NaCl(aq)$				
SOLVE	Each reactant is an ionic compound and is named according to the rules for such compounds. Both reactants are in aqueous solution. One product is a precipitate and the other remains in solution. The equation is translated as follows: Aqueous solutions of barium chloride and sodium chromate react to produce a precipitate of barium chromate plus sodium chloride in aqueous solution.

#### 🌔 MAIN IDEA

# Chemical equations show relative amounts, masses, and progression of chemical reactions.

Chemical equations are very useful in doing quantitative chemical work. The arrow in a balanced chemical equation is like an equal sign. And the chemical equation as a whole is similar to an algebraic equation in that it expresses an equality. Let's examine some of the quantitative information revealed by a chemical equation.

**1.** *The coefficients of a chemical reaction indicate relative, not absolute, amounts of reactants and products.* A chemical equation usually shows the smallest numbers of atoms, molecules, or ions that will satisfy the law of conservation of mass in a given chemical reaction.

Consider the equation for the formation of hydrogen chloride from hydrogen and chlorine.

$$H_2(g) + Cl_2(g) \longrightarrow 2HCl(g)$$

The equation indicates that 1 molecule of hydrogen reacts with 1 molecule of chlorine to produce 2 molecules of hydrogen chloride, resulting in the following molecular ratio of reactants and products.

1 molecule  $H_2$ : 1 molecule  $Cl_2$ : 2 molecules HCl

This ratio shows the smallest possible relative amounts of the reaction's reactants and products. To obtain larger relative amounts, we simply multiply each coefficient by the same number. For example, we could multiply each by a factor of 20. Thus, 20 molecules of hydrogen would react with 20 molecules of chlorine to yield 40 molecules of hydrogen chloride. The reaction can also be considered in terms of amounts in moles: 1 mol of hydrogen molecules reacts with 1 mol of chlorine molecules to yield 2 mol of hydrogen chloride molecules.

2. The relative masses of the reactants and products of a chemical reaction can be determined from the reaction's coefficients. Recall that an amount of an element or compound in moles can be converted to a mass in grams by multiplying by the appropriate molar mass. We know that 1 mol of hydrogen reacts with 1 mol of chlorine to yield 2 mol of hydrogen chloride. The relative masses of the reactants and products are calculated as follows.

$$1 \operatorname{mol} \operatorname{H}_{2} \times \frac{2.02 \text{ g H}_{2}}{\operatorname{mol} \operatorname{H}_{2}} = 2.02 \text{ g H}_{2}$$
$$1 \operatorname{mol} \operatorname{Cl}_{2} \times \frac{70.90 \text{ g Cl}_{2}}{\operatorname{mol} \operatorname{Cl}_{2}} = 70.90 \text{ g Cl}_{2}$$
$$2 \operatorname{mol} \operatorname{HCl} \times \frac{36.46 \text{ g HCl}}{\operatorname{mol} \operatorname{HCl}} = 72.92 \text{ g HCl}$$

The chemical equation shows that 2.02 g of hydrogen will react with 70.90 g of chlorine to yield 72.92 g of hydrogen chloride.

**3.** The reverse reaction for a chemical equation has the same relative amounts of substances as the forward reaction. Because a chemical equation is like an algebraic equation, the equality can be read in either direction. Reading the hydrogen chloride formation equation, we can see that 2 molecules of hydrogen chloride break down to form 1 molecule of hydrogen plus 1 molecule of chlorine. Similarly, 2 mol (72.92 g) of hydrogen chloride yield 1 mol (2.02 g) of hydrogen and 1 mol (70.90 g) of chlorine. **Figure 1.6** summarizes the above ideas.

#### FIGURE 1.6

**Interpreting Chemical Equations** This representation of the reaction of hydrogen and chlorine to yield hydrogen chloride shows several ways to interpret the quantitative information of a chemical reaction.

We have seen that a chemical equation provides useful quantitative information about a chemical reaction. However, there is also important information that is *not* provided by a chemical equation. For instance, an equation gives no indication of whether a reaction will actually occur. A chemical equation can be written for a reaction that may not even take place. Some guidelines about the types of simple reactions that can be expected to occur are given in later sections. And later chapters provide additional guidelines for other types of reactions. In all these guidelines, it is important to remember that experimentation forms the basis for confirming that a particular chemical reaction will occur.

In addition, chemical equations give no information about the speed at which reactions occur or about how the bonding between atoms or ions changes during the reaction. These aspects of chemical reactions are discussed in the chapter "Reaction Kinetics."

#### MAIN IDEA Chemical equations can be balanced with step-by-step inspection.

Most of the equations in the remainder of this chapter can be balanced by inspection. The following procedure demonstrates how to master balancing equations by inspection using a step-by-step approach. The equation for the decomposition of water (see **Figure 1.7**) will be used as an example.

**1.** *Identify the names of the reactants and the products, and write a word equation.* The word equation for the reaction shown in **Figure 1.7** is written as follows.

water  $\longrightarrow$  hydrogen + oxygen

2. Write a formula equation by substituting correct formulas for the names of the reactants and the products. We know that the formula for water is  $H_2O$ . And recall that both hydrogen and oxygen exist as diatomic molecules. Therefore, their correct formulas are  $H_2$  and  $O_2$ , respectively.

$$H_2O(l) \longrightarrow H_2(g) + O_2(g) \text{ (not balanced)}$$

#### FIGURE 1.7

#### Decomposition of Water

When an electric current is passed through water that has been made slightly conductive, the water molecules break down to yield hydrogen (in tube at right) and oxygen (in tube at left). Bubbles of each gas are evidence of the reaction. Note that twice as much hydrogen as oxygen is produced.

- **3.** Balance the formula equation according to the law of conservation of *mass*. This last step is done by trial and error. Coefficients are changed and the numbers of atoms are counted on both sides of the equation. When the numbers of each type of atom are the same for both the products and the reactants, the equation is balanced. The trial-and-error method of balancing equations is made easier by the use of the following guidelines.
  - Balance the different types of atoms one at a time.
  - First balance the atoms of elements that are combined and that appear only once on each side of the equation.
  - Balance polyatomic ions that appear on both sides of the equation as single units. Look closely to see if these ions are enclosed in parentheses, and count the individual atoms accordingly.
  - Balance H atoms and O atoms after atoms of all other elements have been balanced.

The formula equation in our example shows that there are two oxygen atoms on the right and only one on the left. To balance oxygen atoms, the number of  $H_2O$  molecules must be increased. Placing the coefficient 2 before  $H_2O$  gives the necessary two oxygen atoms on the left.

$$2H_2O(l) \longrightarrow H_2(g) + O_2(g)$$
 (partially balanced)

The coefficient 2 in front of  $H_2O$  has upset the balance of hydrogen atoms. Placing the coefficient 2 in front of hydrogen,  $H_2$ , on the right, gives an equal number of hydrogen atoms (4) on both sides of the equation.

$$2H_2O(l) \longrightarrow 2H_2(g) + O_2(g)$$

**4.** *Count atoms to be sure that the equation is balanced.* Make sure that equal numbers of atoms of each element appear on both sides of the arrow.

$$2H_2O(l) \longrightarrow 2H_2(g) + O_2(g)$$
$$(4H + 2O) = (4H) + (2O)$$

Occasionally at this point, the coefficients do not represent the smallest possible whole-number ratio of reactants and products. When this happens, the coefficients should be divided by their greatest common factor in order to obtain the smallest possible whole-number coefficients.

Balancing chemical equations by inspection becomes easier as you gain experience. Learn to avoid the most common mistakes: (1) writing incorrect chemical formulas for reactants or products and (2) trying to balance an equation by changing subscripts. Remember that subscripts cannot be added, deleted, or changed. Eventually, you will probably be able to skip writing the word equation and each separate step. You may even may develop several "tricks" of your own for deciding how best to deal with certain compounds and polyatomic ions. Remember, there is no one, singular way to go about balancing a chemical equation, so you should not be afraid to use a method you feel works best for you. However, *do not* leave out the final step of counting atoms to be sure the equation is balanced.

**CHECK FOR UNDERSTANDING Discuss** Why should subscripts not be changed when balancing chemical equations?

#### Writing Word, Formula, and Balanced Chemical Equations

**Sample Problem C** The reaction of zinc with aqueous hydrochloric acid produces a solution of zinc chloride and hydrogen gas. This reaction is shown in Figure 1.8. Write a balanced chemical equation for the reaction.

Learn It! Video

PREMIUM CONTENT

**Practice** Answers in Appendix E

- Write word, formula, and balanced chemical equations for each of the following reactions:
   a. Solid magnesium and aqueous hydrochloric acid react to produce aqueous magnesium
  - chloride and hydrogen gas.b. Aqueous nitric acid reacts with solid magnesium hydroxide to produce aqueous magnesium nitrate and water.
- **2.** Solid calcium metal reacts with water to form aqueous calcium hydroxide and hydrogen gas. Write a balanced chemical equation for this reaction.

OCharles D. Winters/Photo Researchers, Inc

#### **Balancing Chemical Equations**

**Sample Problem D** Solid aluminum carbide,  $Al_4C_3$ , reacts with water to produce methane gas and solid aluminum hydroxide. Write a balanced chemical equation for this reaction.

#### SOLVE

The reactants are aluminum carbide and water. The products are methane and aluminum hydroxide. The formula equation is written as follows.

 $Al_4C_3(s) + H_2O(l) \longrightarrow CH_4(g) + Al(OH)_3(s)$  (not balanced)

Begin balancing the formula equation by counting either aluminum atoms or carbon atoms. (Remember that hydrogen and oxygen atoms are balanced last.) There are four Al atoms on the left. To balance Al atoms, place the coefficient 4 before  $Al(OH)_3$  on the right.

 $Al_4C_3(s) + H_2O(l) \longrightarrow CH_4(g) + 4Al(OH)_3(s)$  (partially balanced)

Now balance the carbon atoms. With three C atoms on the left, the coefficient 3 must be placed before  $CH_4$  on the right.

 $Al_4C_3(s) + H_2O(l) \longrightarrow 3CH_4(g) + 4Al(OH)_3(s)$  (partially balanced)

Balance oxygen atoms next because oxygen, unlike hydrogen, appears only once on each side of the equation. There is one O atom on the left and 12 O atoms in the four  $Al(OH)_3$  formula units on the right. Placing the coefficient 12 before  $H_2O$  balances the O atoms.

 $Al_4C_3(s) + 12H_2O(l) \longrightarrow 3CH_4(g) + 4Al(OH)_3(s)$ 

This leaves the hydrogen atoms to be balanced. There are 24 H atoms on the left. On the right, there are 12 H atoms in the methane molecules and 12 in the aluminum hydroxide formula units, totaling 24 H atoms. The H atoms are balanced.

$$Al_4C_3(s) + 12H_2O(l) \longrightarrow 3CH_4(g) + 4Al(OH)_3(s)$$
  
(4At+3C) + (24t+12C) = (3C+12t+1) + (4At+12t+12C)

The equation is balanced.

#### **Balancing Chemical Equations**

**Sample Problem E** Aluminum sulfate and calcium hydroxide are used in a water-purification process. When added to water, they dissolve and react to produce two insoluble products, aluminum hydroxide and calcium sulfate. These products settle out, taking suspended solid impurities with them. Write a balanced chemical equation for the reaction.

Each of the reactants and products is an ionic compound. Recall that the formulas of ionic compounds are determined by the charges of the ions composing each compound. The formula reaction is thus written as follows.

 $Al_2(SO_4)_3 + Ca(OH)_2 \longrightarrow Al(OH)_3 + CaSO_4$  (not balanced)

Continued

#### Balancing Chemical Equations (continued)

There is one Ca atom on each side of the equation, so the calcium atoms are already balanced. There are two Al atoms on the left and one Al atom on the right. Placing the coefficient 2 in front of  $Al(OH)_3$  produces the same number of Al atoms on each side of the equation.

 $Al_2(SO_4)_3 + Ca(OH)_2 \longrightarrow 2Al(OH)_3 + CaSO_4$  (partially balanced)

Next, checking  $SO_4^{2-}$  ions shows that there are three  $SO_4^{2-}$  ions on the left side of the equation and only one on the right side. Placing the coefficient 3 before  $CaSO_4$  gives an equal number of  $SO_4^{2-}$  ions on each side.

 $Al_2(SO_4)_3 + Ca(OH)_2 \longrightarrow 2Al(OH)_3 + 3CaSO_4$  (partially balanced)

There are now three Ca atoms on the right, however. By placing the coefficient 3 in front of  $Ca(OH)_2$ , we once again have an equal number of Ca atoms on each side. This last step also gives six  $OH^-$  ions on both sides of the equation.

 $\begin{aligned} \operatorname{Al}_{2}(\operatorname{SO}_{4})_{3}(aq) &+ \operatorname{3Ca}(\operatorname{OH})_{2}(aq) \longrightarrow 2\operatorname{Al}(\operatorname{OH})_{3}(s) &+ \operatorname{3CaSO}_{4}(s) \\ (2\operatorname{AI} + \operatorname{3SO}_{4}^{2^{-}}) &+ (\operatorname{3Ca} + \operatorname{6OH}^{-}) &= (2\operatorname{AI} + \operatorname{6OH}^{-}) &+ (\operatorname{3Ca} + \operatorname{3SO}_{4}^{2^{-}}) \end{aligned}$ 

The equation is balanced.

#### **Practice**

- **1.** Write balanced chemical equations for each of the following reactions:
  - a. Solid sodium combines with chlorine gas to produce solid sodium chloride.
  - **b.** When solid copper reacts with aqueous silver nitrate, the products are aqueous copper(II) nitrate and solid silver.
  - **c.** In a blast furnace, the reaction between solid iron(III) oxide and carbon monoxide gas produces solid iron and carbon dioxide gas.

#### SECTION 1 FORMATIVE ASSESSMENT

#### Reviewing Main Ideas

- **1.** Describe the differences between word equations, formula equations, and chemical equations.
- **2.** Write word and formula equations for the reaction in which aqueous solutions of sulfuric acid and sodium hydroxide react to form aqueous sodium sulfate and water.
- **3.** Translate the following chemical equations into sentences:

**a.** 
$$2K(s) + 2H_2O(l) \longrightarrow 2KOH(aq) + H_2(g)$$
  
**b.**  $2Fe(s) + 3Cl_2(g) \longrightarrow 2FeCl_3(s)$ 

**4.** Write the word, formula, and chemical equations for the reaction between hydrogen sulfide gas and oxygen gas that produces sulfur dioxide gas and water vapor.

#### 🝼 Critical Thinking

**5. INTEGRATING CONCEPTS** The reaction of vanadium(II) oxide with iron(III) oxide results in the formation of vanadium(V) oxide and iron(II) oxide. Write the balanced chemical equation.

### WHY IT MATTERS

## Carbon Monoxide Catalyst

# S.T.E.M.

olorless, odorless, and deadly, carbon monoxide, "the silent killer," causes the deaths of hundreds of Americans every year. When fuel does not burn completely in a combustion process, carbon monoxide is produced. Often this occurs in a malfunctioning heater, furnace, or fireplace. When the carbon monoxide is inhaled, it bonds to the hemoglobin in the blood, leaving the body oxygen-starved. Before people realize a combustion device is malfunctioning, it's often too late.

#### $0_2Hb + CO \longrightarrow COHb + 0_2$

Carbon monoxide, CO, has almost 200 times the affinity to bind with the hemoglobin, Hb, in the blood as oxygen. This means that hemoglobin will bind to carbon monoxide rather than oxygen in the body. If enough carbon monoxide is present in the blood, it can be fatal.

Carbon monoxide poisoning can be prevented by installing filters that absorb the gas. After some time, however, filters become saturated, and then carbon monoxide can pass freely into the air. The best way to prevent carbon monoxide poisoning is not just to filter out the gas, but to eliminate it completely.

The solution came to research chemists at NASA who were working on a problem with a space-based laser. In order to operate properly, NASA's space-based carbon dioxide laser needed to be fed a continuous supply of  $CO_2$ . This was necessary because as a byproduct of its operation, the laser degraded some of the  $CO_2$  into carbon monoxide and oxygen. To address this problem, NASA scientists developed a catalyst made of tin oxide and platinum that oxidized the waste carbon monoxide back into carbon dioxide. The NASA scientists then realized that this catalyst had the potential to be used in many applications here on Earth, including removing carbon monoxide from houses and other buildings. Typically, a malfunctioning heater circulates the carbon monoxide it produces through its air intake system back into a dwelling space. Installing the catalyst in the air intake would oxidize any carbon monoxide to nontoxic carbon dioxide before it reentered the room.

"The form of our catalyst is a very thin coating on some sort of a support, or substrate as we call it," says NASA chemist David Schryer. "And that support, or substrate, can be any one of a number of things. The great thing about a catalyst is that the only thing that matters about it is its surface. So a catalyst can be incredibly thin and still be very effective."

The idea of using catalysts to oxidize gases is not a new one. Catalytic converters in cars oxidize carbon monoxide and unburned hydrocarbons to minimize pollution. Many substances are oxidized into new materials for manufacturing purposes. But both of these types of catalytic reactions occur at very high temperatures. NASA's catalyst is special, because it's able to eliminate carbon monoxide at room temperature.

According to David Schryer, low-temperature catalysts constitute a whole new class of catalysts with abundant applications for the future.

#### Questions

- **1.** How did NASA's research on the space-based carbon dioxide laser result in a benefit for consumers?
- 2. According to the chemical reaction, if there are 4.5 mol of oxygenated hemoglobin present in an excess of carbon monoxide, how many moles of hemoglobin would release oxygen and bind to carbon monoxide? Explain your answer.

#### **SECTION 2**

#### **Main Ideas**

Substances are combined in synthesis reactions.

Substances are broken down in decomposition reactions.

One element replaces another in single-displacement reactions.

In double-displacement reactions, two compounds exchange ions.

Combustion reactions involve oxygen.

#### > VIRCINIA STANDARDS

**CH.3e** The student will investigate and understand how conservation of energy and matter is expressed in chemical formulas and balanced equations. Key concepts include: reaction types. **CH.3.EKS-10** 

# Types of Chemical Reactions

#### Key Terms

synthesis reaction decomposition reaction electrolysis single-displacement reaction double-displacement reaction combustion reaction

Thousands of known chemical reactions occur in living systems, in industrial processes, and in chemical laboratories. Often it is necessary to predict the products formed in one of these reactions. Memorizing the equations for so many chemical reactions would be a difficult task. It is therefore more useful and realistic to classify reactions according to various similarities and regularities. This general information about reaction types can then be used to predict the products of specific reactions.

There are several ways to classify chemical reactions, and none are entirely satisfactory. The classification scheme described in this section provides an introduction to five basic types of reactions: synthesis, decomposition, single-displacement, double-displacement, and combustion reactions. In later chapters, you will be introduced to categories that are useful in classifying other types of chemical reactions.

#### MAIN IDEA Substances are combined in synthesis reactions.

In a synthesis reaction, also known as a composition reaction, two or more substances combine to form a new compound. This type of reaction is represented by the following general equation:

 $A + X \longrightarrow AX$ 

A and X can be elements or compounds. AX is a compound. The following examples illustrate several kinds of synthesis reactions.

#### **Reactions of Elements with Oxygen and Sulfur**

One simple type of synthesis reaction is the combination of an element with oxygen to produce an *oxide* of the element. Almost all metals react with oxygen to form oxides. For example, when a thin strip of magnesium metal is placed in an open flame, it burns with bright white light. When the metal strip is completely burned, only a fine white powder of magnesium oxide is left. This chemical reaction, shown in **Figure 2.1** on the next page, is represented by the following equation:

 $2Mg(s) + O_2(g) \longrightarrow 2MgO(s)$ 

The other Group 2 elements react in a similar manner, forming oxides with the formula MO, where M represents the metal. The Group 1 metals form oxides with the formula  $M_2O$ , for example, Li<sub>2</sub>O. The Group 1 and Group 2 elements react similarly with sulfur, forming *sulfides* with the formulas  $M_2S$  and MS, respectively. Examples of these types of synthesis reactions are shown below.

$$16\text{Rb}(s) + \text{S}_8(s) \longrightarrow 8\text{Rb}_2\text{S}(s)$$
$$8\text{Ba}(s) + \text{S}_8(s) \longrightarrow 8\text{BaS}(s)$$

Some metals, such as iron, combine with oxygen to produce two different oxides.

$$2Fe(s) + O_2(g) \longrightarrow 2FeO(s)$$
$$4Fe(s) + 3O_2(g) \longrightarrow 2Fe_2O_3(s)$$

In the product of the first reaction, iron is in an oxidation state of +2. In the product of the second reaction, iron is in an oxidation state of +3. The particular oxide formed depends on the conditions surrounding the reactants. Both oxides are shown below in **Figure 2.2**.

Nonmetals also undergo synthesis reactions with oxygen to form oxides. Sulfur, for example, reacts with oxygen to form sulfur dioxide. And when carbon is burned in air, carbon dioxide is produced.

$$S_8(s) + 8O_2(g) \longrightarrow 8SO_2(g)$$
  
 $C(s) + O_2(g) \longrightarrow CO_2(g)$ 

In a limited supply of oxygen, carbon monoxide is formed.

$$2C(s) + O_2(g) \longrightarrow 2CO(g)$$

Hydrogen reacts with oxygen to form dihydrogen monoxide, better known as water.

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(g)$$

#### FIGURE 2.1

#### Synthesis Reaction of Magnesium and Oxygen

(a) Magnesium, Mg, pictured here, undergoes a synthesis reaction with oxygen, O<sub>2</sub>.

(b) The reaction produced magnesium oxide, MgO.

#### FIGURE 2.2

(a) iron(II) oxide, FeO

(b) iron(III) oxide, Fe<sub>2</sub>O<sub>3</sub>

#### **Reactions of Metals with Halogens**

Most metals react with the Group 17 elements, the halogens, to form either ionic or covalent compounds. For example, Group 1 metals react with halogens to form ionic compounds with the formula MX, where M is the metal and X is the halogen. Examples of this type of synthesis reaction include the reactions of sodium with chlorine and potassium with iodine.

$$2\operatorname{Na}(s) + \operatorname{Cl}_{2}(g) \longrightarrow 2\operatorname{NaCl}(s)$$
$$2\operatorname{K}(s) + \operatorname{I}_{2}(g) \longrightarrow 2\operatorname{KI}(s)$$

Group 2 metals react with the halogens to form ionic compounds with the formula MX<sub>2</sub>.

$$Mg(s) + F_{2}(g) \longrightarrow MgF_{2}(s)$$
  
Sr(s) + Br<sub>2</sub>(l)  $\longrightarrow$  SrBr<sub>2</sub>(s)

The halogens undergo synthesis reactions with many different metals. Fluorine in particular is so reactive that it combines with almost all metals. For example, fluorine reacts with sodium to produce sodium fluoride. Similarly, it reacts with cobalt to form cobalt(III) fluoride and with uranium to form uranium(VI) fluoride.

$$2\operatorname{Na}(s) + \operatorname{F}_{2}(g) \longrightarrow 2\operatorname{NaF}(s)$$
$$2\operatorname{Co}(s) + 3\operatorname{F}_{2}(g) \longrightarrow 2\operatorname{CoF}_{3}(s)$$
$$U(s) + 3\operatorname{F}_{2}(g) \longrightarrow U\operatorname{F}_{6}(g)$$

Sodium fluoride, NaF, is added to municipal water supplies in trace amounts to provide fluoride ions, which help to prevent tooth decay in the people who drink the water. Cobalt(III) fluoride,  $CoF_3$ , is a strong fluorinating agent. And natural uranium is converted to uranium(VI) fluoride,  $UF_6$ , as the first step in the production of uranium for use in nuclear power plants.

#### **Synthesis Reactions with Oxides**

*Active* metals are highly reactive metals. Oxides of active metals react with water to produce metal hydroxides. Calcium oxide, CaO, also known as lime or quicklime, is manufactured in large quantities. The addition of water to lime to produce  $Ca(OH)_2$ , which is also known as slaked lime, is a crucial step in the setting of cement.

$$CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(s)$$

Calcium hydroxide also is an ingredient in some stomach antacids, as shown in **Figure 2.3**. In the stomach, it reacts with hydrochloric, neutralizing its effects. These *neutralization* reactions are dealt with in more detail in the chapter on acids and bases.

Many oxides of nonmetals in the upper-right portion of the periodic table react with water to produce oxyacids. For example, sulfur dioxide, SO<sub>2</sub>, reacts with water to produce sulfurous acid.

#### FIGURE 2.3

**Calcium Hydroxide** Calcium hydroxide, a base, can be used to *neutralize* hydrochloric acid in your stomach. The chapter "Acids and Bases" describes neutralization reactions in more detail.

$$SO_2(g) + H_2O(l) \longrightarrow H_2SO_3(aq)$$

In air polluted with  $SO_{2'}$  sulfurous acid further reacts with oxygen to form sulfuric acid, one of the main ingredients in *acid precipitation*, known more familiarly as *acid rain*.

$$2H_2SO_3(aq) + O_2(g) \longrightarrow 2H_2SO_4(aq)$$

Certain metal oxides and nonmetal oxides react with each other in synthesis reactions to form salts. For example, calcium sulfite is formed by the reaction of calcium oxide and sulfur dioxide.

$$CaO(s) + SO_2(g) \longrightarrow CaSO_3(s)$$

#### MAIN IDEA Substances are broken down in decomposition reactions.

In a decomposition reaction, a single compound undergoes a reaction that produces two or more simpler substances. Decomposition reactions are the opposite of synthesis reactions and are represented by the following general equation.

 $AX \longrightarrow A + X$ 

AX is a compound. A and X can be elements or compounds.

Most decomposition reactions take place only when energy in the form of electricity or heat is added. Examples of several types of decomposition reactions are given in the following sections.

#### **Decomposition of Binary Compounds**

The simplest kind of decomposition reaction is the decomposition of a binary compound into its elements. We have already examined one example of a decomposition reaction, the decomposition of water into hydrogen and oxygen. An electric current passed through water will decomposes it into its constituent elements. The decomposition of a substance by an electric current is called electrolysis.

 $2H_2O(l) \xrightarrow{\text{electricity}} 2H_2(g) + O_2(g)$ 

Notice the word *electricity* above the reaction arrow.

Oxides of the less-active metals, which are located in the lower center of the periodic table, decompose into their elements when heated. Joseph Priestley, one of the founders of modern chemistry, discovered oxygen through such a decomposition reaction in 1774, when he heated mercury(II) oxide to produce mercury and oxygen.

 $2 \text{HgO}(s) \xrightarrow{\Delta} 2 \text{Hg}(l) + O_2(g)$ 

This reaction is shown in Figure 2.4 on the following page.

CHECK FOR UNDERSTANDING Apply Using your knowledge of synthesis reactions, explain the relationship between air pollution and acid rain.

#### FIGURE 2.4

#### **Decomposition Reaction**

When mercury(II) oxide (the red-orange substance in the bottom of the test tube) is heated, it decomposes into oxygen and metallic mercury, which can be seen as droplets on the inside wall of the test tube.

CRITICAL THINKING Apply What are the products of this reaction?

#### **Decomposition of Metal Carbonates**

When a metal carbonate is heated, it breaks down to produce a metal oxide and carbon dioxide gas. For example, calcium carbonate decomposes to produce calcium oxide and carbon dioxide.

$$CaCO_3(s) \xrightarrow{\Delta} CaO(s) + CO_2(g)$$

#### **Decomposition of Metal Hydroxides**

All metal hydroxides except those containing Group 1 metals decompose when heated to yield metal oxides and water. For example, calcium hydroxide decomposes to produce calcium oxide and water.

$$Ca(OH)_2(s) \xrightarrow{\Delta} CaO(s) + H_2O(g)$$

#### **Decomposition of Metal Chlorates**

When a metal chlorate is heated, it decomposes to produce a metal chloride and oxygen. For example, potassium chlorate,  $\text{KClO}_3$ , decomposes in the presence of the catalyst  $\text{MnO}_2(s)$  to produce potassium chloride and oxygen.

$$2\mathrm{KClO}_3(s) \xrightarrow{\Delta} 2\mathrm{KCl}(s) + 3\mathrm{O}_2(g)$$

#### **Decomposition of Acids**

Certain acids decompose into nonmetal oxides and water. Carbonic acid is unstable and decomposes readily at room temperature to produce carbon dioxide and water.

$$H_2CO_3(aq) \longrightarrow CO_2(g) + H_2O(l)$$

When heated, sulfuric acid decomposes into sulfur trioxide and water.

$$H_2SO_4(aq) \xrightarrow{\Delta} SO_3(g) + H_2O(l)$$

Sulfurous acid, H<sub>2</sub>SO<sub>3</sub>, decomposes similarly.

# MAIN IDEA One element replaces another in single-displacement reactions.

#### In a single-displacement reaction, also known as a replacement reaction, one element replaces a similar element in a compound. Many singledisplacement reactions take place in aqueous solution. The amount of energy involved in this type of reaction is usually smaller than the amount involved in synthesis or decomposition reactions. Single-displacement reactions can be represented by the following general equations:

$$\begin{array}{c} A + BX \longrightarrow AX + B \\ or \\ Y + BX \longrightarrow BY + X \end{array}$$

A, B, X, and Y are elements. AX, BX, and BY are compounds.

#### **Displacement of a Metal in a Compound by Another Metal**

Aluminum is more active than lead. When solid aluminum is placed in aqueous lead(II) nitrate,  $Pb(NO_3)_2(aq)$ , the aluminum replaces the lead. Solid lead and aqueous aluminum nitrate are formed.

 $2\text{Al}(s) + 3\text{Pb}(\text{NO}_3)_2(aq) \longrightarrow 3\text{Pb}(s) + 2\text{Al}(\text{NO}_3)_3(aq)$ 

#### **Displacement of Hydrogen in Water by a Metal**

The most-active metals, such as those in Group 1, react vigorously with water to produce metal hydroxides and hydrogen. For example, sodium reacts with water to form sodium hydroxide and hydrogen gas.

$$2Na(s) + 2H_2O(l) \longrightarrow 2NaOH(aq) + H_2(g)$$

Less-active metals, such as iron, react with steam to form a metal oxide and hydrogen gas.

$$3\text{Fe}(s) + 4\text{H}_2\text{O}(g) \longrightarrow \text{Fe}_3\text{O}_4(s) + 4\text{H}_2(g)$$

#### **Displacement of Hydrogen in an Acid by a Metal**

The more-active metals react with certain acidic solutions, such as hydrochloric acid and dilute sulfuric acid, replacing the hydrogen in the acid. The reaction products are a metal compound (a salt) and hydrogen gas. For example, when solid magnesium reacts with hydrochloric acid, as shown in **Figure 2.5**, the reaction products are hydrogen gas and aqueous magnesium chloride.

$$Mg(s) + 2HCl(aq) \longrightarrow H_2(g) + MgCl_2(aq)$$

Be careful as you study chemistry to remember that the term *salt* often has a wider definition than simply that of the table salt (sodium chloride) you put on food. Strictly speaking, a salt is any ionic compound formed in the neutralization of an acid by a base.

FIGURE 2.5

#### **Single Displacement**

**Reaction** In this singledisplacement reaction, the hydrogen in hydrochloric acid, HCl, is replaced by magnesium, Mg.

#### **Displacement of Halogens**

In another type of single-displacement reaction, one halogen replaces another halogen in a compound. Fluorine is the most-active halogen. As such, it can replace any of the other halogens in their compounds. Each halogen is less active than the one above it in the periodic table. Therefore, in Group 17 each element can replace any element below it, but not any element above it. For example, while chlorine can replace bromine in potassium bromide, it cannot replace fluorine in potassium fluoride. The reaction of chlorine with potassium bromide produces bromine and potassium chloride, whereas the combination of fluorine and sodium chloride produces sodium fluoride and solid chlorine.

 $\operatorname{Cl}_2(g) + 2\operatorname{KBr}(aq) \longrightarrow 2\operatorname{KCl}(aq) + \operatorname{Br}_2(l)$ 

 $F_2(g) + 2NaCl(aq) \longrightarrow 2NaF(aq) + Cl_2(g)$ 

 $\operatorname{Br}_2(l) + \operatorname{KCl}(aq) \longrightarrow$  no reaction

#### MAIN IDEA In double-displacement reactions, two compounds exchange ions.

In double-displacement reactions, the ions of two compounds exchange places in an aqueous solution to form two new compounds. One of the compounds formed is usually a precipitate, an insoluble gas that bubbles out of the solution, or a molecular compound, usually water. The other compound is often soluble and remains dissolved in solution. A doubledisplacement reaction is represented by the following general equation.

$$AX + BY \longrightarrow AY + BX$$

A, X, B, and Y in the reactants represent ions. AY and BX represent ionic or molecular compounds.

#### **Formation of a Precipitate**

The formation of a precipitate occurs when the cations of one reactant combine with the anions of another reactant to form an insoluble or slightly soluble compound. For example, when an aqueous solution of potassium iodide is added to an aqueous solution of lead(II) nitrate, the yellow precipitate lead(II) iodide forms. This is shown in **Figure 2.6**.

 $2\text{KI}(aq) + \text{Pb}(\text{NO}_3)_2(aq) \longrightarrow \text{PbI}_2(s) + 2\text{KNO}_3(aq)$ 

The precipitate forms as a result of the very strong attractive forces between the  $Pb^{2+}$  cations and the I<sup>-</sup> anions. The other product is the water-soluble salt potassium nitrate,  $KNO_3$ . The potassium and nitrate ions do not take part in the reaction. They remain in solution as aqueous ions and therefore are often referred to as *spectator ions*. The guidelines that help identify which ions form a precipitate and which ions remain in solution are developed in a later chapter on ions in aqueous solutions.

#### FIGURE 2.6

#### **Double-Displacement Reaction**

The double-displacement reaction between aqueous lead(II) nitrate,  $Pb(NO_3)_2(aq)$ , and aqueous potassium iodide, KI(aq), yields the precipitate lead(II) iodide,  $PbI_2(s)$ .

#### **Formation of a Gas**

In some double-displacement reactions, one of the products is an insoluble gas that bubbles out of the mixture. For example, iron(II) sulfide reacts with hydrochloric acid to form hydrogen sulfide gas and iron(II) chloride.

$$FeS(s) + 2HCl(aq) \longrightarrow H_2S(g) + FeCl_2(aq)$$

#### **Formation of Water**

In some double-displacement reactions, a very stable molecular compound, such as water, is one of the products. For example, hydrochloric acid reacts with an aqueous solution of sodium hydroxide to yield aqueous sodium chloride and water.

$$HCl(aq) + NaOH(aq) \longrightarrow NaCl(aq) + H_2O(l)$$

#### MAIN IDEA Combustion reactions involve oxygen.

In a combustion reaction, a substance combines with oxygen, releasing a large amount of energy in the form of light and heat. The burning of natural gas, propane, gasoline, and wood are also examples of combustion reactions. For example, the propane,  $C_3H_8$ , combustion results in the production of carbon dioxide and water vapor.

$$C_3H_8(g) + 5O_2(g) \longrightarrow 3CO_2(g) + 4H_2O(g)$$

The combustion of hydrogen, shown in Figure 2.7, produces water vapor.

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(g)$$

#### WHY IT MATTERS

#### **Fluoridation and Tooth Decay**

The main component of tooth enamel is a mineral called hydroxyapatite,  $Ca_5(PO_4)_3OH$ . Some foods contain acids or produce acids in the mouth, and acid dissolves tooth enamel, which leads to tooth decay. One way to help prevent tooth decay is by using fluoride. Fluoride reacts with hydroxyapatite in a doubledisplacement reaction. It displaces the OH<sup>-</sup> group in hydroxyapatite to produce fluorapatite,  $Ca_{F}(PO_{4})_{2}F$ . Studies show that calcium fluorapatite is about 20% less soluble than hydroxyapatite in acid. Therefore, fluoride lowers the incidence of tooth decay.

#### FIGURE 2.7

#### **Combustion Reaction of Hydrogen**

(a) The candle supplies heat to the hydrogen and oxygen in the balloon.

(b) The heat triggers the explosive combustion reaction.

#### **V** CRITICAL THINKING

**Explain** In combustion reactions, substances combined with oxygen usually result in a fire or explosion. What remains afterwards is usually ash or fine particles, which often do not contain all of the elements found in the reactants. Explain what happens to the missing elements in terms of conservation of matter.

#### SECTION 2 FORMATIVE ASSESSMENT

#### Reviewing Main Ideas

- 1. List five types of chemical reactions.
- **2.** Classify each of the following reactions as a synthesis, decomposition, single-displacement, double-displacement, or combustion reaction:

**a.** 
$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$
  
**b.**  $2Li(s) + 2H_2O(l) \longrightarrow 2LiOH(aq) + H_2(g)$   
**c.**  $2NaNO_3(s) \longrightarrow 2NaNO_2(s) + O_2(g)$   
**d.**  $2C_6H_{14}(l) + 19O_2(g) \longrightarrow 12CO_2(g) + 14H_2O(l)$ 

- **3.** For each of the following reactions, identify the missing reactant(s) or products(s) and then balance the resulting equation. Note that each empty slot may require one or more substances.
  - **a.** synthesis:  $\longrightarrow$  Li<sub>2</sub>O
  - **b.** decomposition:  $Mg(ClO_3)_2 \longrightarrow$  \_\_\_\_\_
  - **c.** double displacement:  $HNO_3 + Ca(OH)_2 \longrightarrow \_\_\_$ **d.** combustion:  $C_5H_{12} + O_2 \longrightarrow \_\_\_$

- **4.** For each of the following reactions, write the missing product(s) and then balance the resulting equation. Identify each reaction by type.
  - **a.**  $Br_2 + KI \longrightarrow$
  - **b.** NaClO<sub>3</sub>  $\xrightarrow{\Delta}$  \_\_\_\_\_
  - **c.**  $C_7H_{14} + O_2 \longrightarrow \_$
  - **d.**  $\operatorname{CuCl}_2 + \operatorname{Na}_2 S \longrightarrow \_$

#### **V** Critical Thinking

**5. INFERRING RELATIONSHIPS** In an experiment, an iron sample is oxidized to iron(III) oxide by oxygen, which is generated in the thermal decomposition of potassium chlorate. Write the two chemical reactions in the correct sequence.

# Activity Series of the Elements

Key Term activity series

The ability of an element to react is referred to as the element's *activity*. The more readily an element reacts with other substances, the greater its activity is. **An activity series** is a list of elements organized according to the ease with which the elements undergo certain chemical reactions. For metals, greater activity means a greater ease of *loss* of electrons, to form positive ions. For nonmetals, greater activity means a greater ease of *gain* of electrons, to form negative ions.

#### MAIN IDEA An activity series helps determine what substances will displace others in chemical reactions.

The order in which the elements are listed is usually determined by single-displacement reactions. The most-active element, placed at the top in the series, can replace each of the elements below it from a compound in a single-displacement reaction. An element farther down can replace any element below it but not any above it. For example, in the discussion of single-displacement reactions in Section 2, it was noted that each halogen will react to replace any halogen listed below it in the periodic table. Therefore, an activity series for the Group 17 elements lists them in the same order, from top to bottom, as they appear in the periodic table. This is shown in **Figure 3.1** on the next page.

As mentioned in Section 1, the fact that a chemical equation can be written does not necessarily mean that the reaction it represents will actually take place. Activity series are used to help predict whether certain chemical reactions will occur. For example, according to the activity series for metals in **Figure 3.1**, aluminum replaces zinc. Therefore, we could predict that the following reaction does occur.

 $2Al(s) + 3ZnCl_2(aq) \longrightarrow 3Zn(s) + 2AlCl_3(aq)$ 

Cobalt, however, cannot replace sodium. Therefore, we write the following:

 $Co(s) + 2NaCl(aq) \longrightarrow$  no reaction

It is important to remember that like many other aids used to predict the products of chemical reactions, activity series are based on experiment. The information that they contain is used as a general guide for predicting reaction outcomes.

#### **SECTION 3**

Main Ideas

An activity series helps determine what substances will displace others in chemical reactions.

#### VIRGINIA STANDARDS

**CH.1.j** The student will investigate and understand that experiments in which variables are measured, analyzed, and evaluated produce observations and verifiable data. Key concepts include: the use of current applications to reinforce chemistry concepts. **CH.2.EKS-10** 

Such experimental observations are the basis for the activity series shown in Figure 3.1. For example, the activity series reflects the fact that some metals (potassium, for example) react vigorously with water and acids, replacing hydrogen to form new compounds. Other metals, such as iron or zinc, replace hydrogen in acids such as hydrochloric acid but react with water only when the water is hot enough to become steam. Nickel, however, will replace hydrogen in acids but will not react with steam at all. And gold will not react with individual acids or water, either as a liquid or as steam. If you look closely at the fairly unreactive metals in this activity series, you'll notice instantly that they represent the so-called precious metals that are very important to commerce. The ability of these metals to "stay intact" and not react with such things as water and acids, which are everywhere, should give you a clue as to why they have come to hold such great value by cultures all around the world.

#### **FIGURE 3.1**

#### **Activity Series**

**Sample Problem F** Using the activity series shown in Figure 3.1, explain whether each of the possible reactions listed below will occur. For those reactions that will occur, predict what the products will be.

a. Zn(s) + H <sub>2</sub> O( $I$ ) $\xrightarrow{50^{\circ}C}$ c. Cd(s) + Pb(NO <sub>3</sub> ) <sub>2</sub> (aq)			
SOLVE	<ul> <li>a. This is a reaction between a metal and water at 50°C. Zinc reacts with water only when it is hot enough to be steam. Therefore, no reaction will occur.</li> <li>b. Any metal more active than silver will react with oxygen to form an oxide. Tin is above silver in the activity series. Therefore, a reaction will occur, and the product will be a tin oxide, either SnO or SnO2.</li> <li>c. An element will replace any element below it in the activity series from a compound in aqueous solution. Cadmium is above lead, and therefore a reaction will occur to produce lead, Pb, and cadmium nitrate, Cd(NO3)2.</li> <li>d. Any metal more active than hydrogen will replace hydrogen from an acid. Copper is not above hydrogen in the series. Therefore, no reaction will occur.</li> </ul>		
<ul> <li>Practice Answers in Appendix F</li> <li>1. Using the activity series shown in Figure 3.1, predict whether each of the possible reactions listed below will occur. For the reactions that will occur, write the products and balance the equation.</li> <li>a. Cr(s) + H<sub>2</sub>O(l) → c. Cd(s) + 2HBr(aq) → b. Pt(s) + O<sub>2</sub>(g) → d. Mg(s) + steam →</li> <li>2. Identify the element that replaces hydrogen from acids but cannot replace tin from its compounds.</li> <li>3. According to Figure 3.1, what is the most-active transition metal?</li> </ul>			

#### SECTION 3 FORMATIVE ASSESSMENT

#### Reviewing Main Ideas

- **1.** How is the activity series useful in predicting chemical behavior?
- **2.** Based on the activity series, predict whether each of the following possible reactions will occur:
  - **a.** Ni(s) + H<sub>2</sub>O(l)  $\longrightarrow$  \_\_\_\_\_
  - **b.**  $\operatorname{Br}_2(l) + \operatorname{KI}(aq) \longrightarrow$
  - **c.**  $\operatorname{Au}(s) + \operatorname{HCl}(aq) \longrightarrow$
  - **d.**  $Cd(s) + HCl(aq) \longrightarrow$
  - **e.**  $Mg(s) + Co(NO_3)_2(aq) \longrightarrow$

**3.** For each of the reactions in item 2 that will occur, write the products and balance the equation.

#### Critical Thinking

**4. PREDICTING OUTCOMES** A mixture contains cobalt metal, copper metal, and tin metal. This mixture is mixed with nickel nitrate. Which metals, if any, will react? Write the chemical equation for any reaction.

## WHY IT MATTERS

# Combustion Synthesis

# S.T.E.M.

hat do aerospace materials, cutting tools, catalytic materials, ceramic engine parts, ball bearings, high-temperature superconductors, hydrogen storage, and fuel cells have in common? They are made of ceramics, composites, and other advanced materials.

Conventional techniques used to make these materials consist of a high-temperature furnace, with temperatures ranging from 500°C to 2000°C, to supply the energy needed for the reaction to take place. Because these furnaces may reach only 2000°C, it may take minutes to hours to convert reactants to solid-state products, and the mixtures are heated unevenly. As a result, flaws can be introduced into the structures, which can cause stress points in the materials.

A different high-temperature technique is *combustion synthesis*, which generates its own energy to keep the reaction continuing. Once the reactant mixture is ignited, a heat wave moves through the sample, producing the solid-state product. The mixture can reach temperatures up to 4000°C, twice what is possible with conventional high-temperature furnaces. Combustion synthesis also allows reactions to be completed in just seconds. Hence, this technique produces the desired material faster and requires less supplied energy than conventional techniques do. In addition, the intense and quick heating produces materials that are chemically homogeneous. More than 500 compounds, such as lightweight and heat-resistant aerospace materials, are created by combustion synthesis.

In a typical combustion synthesis procedure, the reactant powders are mixed and then pressed into a cylindrical pellet. The pellet is ignited by an intense heat source, such as an electrically heated coil or a laser. Because the combustionsynthesis reaction is very exothermic, the reaction is self-propagating, and the process does not need any further input of energy. This type of self-propagation is called a *reaction wave*, in which the reaction propagates through the starting material in a self-sustained manner. Therefore, compared with conventional high-temperature methods, this technique is an energy-saving process. In addition, the high temperatures and short reaction times can produce materials that would not be synthesized under conventional conditions. Currently, scientists are studying reaction waves, including how they move through the initial mixtures. As scientists better understand the characteristics of combustion synthesis, they can refine the technique to be more useful in advanced materials production.

#### Questions

- **1.** Why is this technique called *combustion synthesis*?
- **2.** Why might this technique result in a more chemically homogeneous material?

Superconducting ceramics, like those used to make supercooled electromagnets, are formed using a combustion synthesis reaction.

# Math Tutor Balancing Chemical Equations

A chemical equation is a written expression of an actual chemical reaction in which certain atoms, ions, or molecules become rearranged in a specific way. Therefore, the equation must represent exactly what happens in the reaction. Recall that atoms are never created or destroyed in chemical reactions. A balanced chemical equation shows that all of the atoms present in reactants are still present in products.

#### **Problem-Solving TIPS**

(

- First, identify reactants and products. (You may find it helpful to write a word equation first.)
- Using correct formulas and symbols, write an unbalanced equation for the reaction.
- Balance atoms one element at a time by inserting coefficients.
- Identify elements that appear in only one reactant and one product, and balance the atoms of those elements first.
- If a polyatomic ion appears on both sides of the equation, treat it as a single unit.
- Double-check to be sure that the number of atoms of each element is the same on both sides of the equation.

#### Sample

When an aqueous solution of ammonium sulfate,  $(NH_4)_2SO_4(aq)$ , is combined with an aqueous solution of silver nitrate,  $AgNO_3(aq)$ , a precipitate of solid silver sulfate,  $Ag_2SO_4(s)$ , forms, leaving ammonium nitrate,  $NH_4NO_3(aq)$ , in solution. Balance the equation for this reaction.

As before, first write an equation with correct formulas for all reactants and products.

$$(NH_4)_2SO_4(aq) + AgNO_3(aq) \longrightarrow NH_4NO_3(aq) + Ag_2SO_4(s)$$

If you compare the number of silver atoms on each side, you can see that the equation is not balanced. This equation may look very complex, but it is really fairly simple. In many reactions involving polyatomic ions such as sulfate, nitrate, and ammonium, the ions do not change. In the equation above, you can see that  $NO_3$  is present on both sides, as are  $SO_4$  and  $NH_4$ . You can balance the equation by treating the groups as if they were single atoms. To balance the  $NH_4$  groups, place a 2 in front of  $NH_4NO_3$ . This gives you two ammonium groups on the left and two on the right. Now, because you have two nitrate groups on the right, place a 2 in front of  $AgNO_3$  to give two nitrate groups on the left. Finally, check silver atoms and sulfate groups, and you find that they balance.

 $(NH_4)_2SO_4(aq) + 2AgNO_3(aq) \longrightarrow 2NH_4NO_3(aq) + Ag_2SO_4(s)$ 

#### **Practice**

**1.** When propane burns completely in air, the reaction forms carbon dioxide and water vapor. Balance the equation for this reaction.

$$C_3H_8 + O_2 \longrightarrow CO_2 + H_2O$$

- **2.** Balance the following chemical equations:
  - **a.**  $\operatorname{KI}(aq) + \operatorname{Cl}_2(g) \longrightarrow \operatorname{KCl}(aq) + \operatorname{I}_2(s)$
  - **b.**  $Al(s) + H_2SO_4(aq) \longrightarrow Al_2(SO_4)_3(aq) + H_2(g)$

## CHAPTER 8 Review

#### **SECTION 1**

### Describing Chemical Reactions

#### **REVIEWING MAIN IDEAS**

- **1.** List four observations that indicate that a chemical reaction may be taking place.
- **2.** List the three requirements for a correctly written chemical equation.
- **3. a.** What is meant by the term *coefficient* in relation to a chemical equation?
  - **b.** How does the presence of a coefficient affect the number of atoms of each type in the formula that the coefficient precedes?
- **4.** Give an example of a word equation, a formula equation, and a chemical equation.
- **5.** What quantitative information is revealed by a chemical equation?
- **6.** What limitations are associated with the use of both word and formula equations?
- **7.** Define each of the following terms:
  - a. aqueous solution
  - **b.** catalyst
  - c. reversible reaction
- 8. Write formulas for each of the following compounds:a. potassium hydroxide
  - **b.** calcium nitrate
  - **c.** sodium carbonate
  - **d.** carbon tetrachloride
  - **e.** magnesium bromide
- **9.** What four guidelines are useful in balancing an equation?
- **10.** How many atoms of each type are represented in each of the following?
  - a.  $3N_2$  f.  $5Fe(NO_3)_2$  

     b.  $2H_2O$  g.  $4Mg_3(PO_4)_2$  

     c.  $4HNO_3$  h.  $2(NH_4)_2SO_4$  

     d.  $2Ca(OH)_2$  i.  $6Al_2(SeO_4)_3$  

     e.  $3Ba(ClO_3)_2$  j.  $4C_3H_8$

#### **PRACTICE PROBLEMS**

- **11.** Write the chemical equation that relates to each of the following word equations. Include symbols for physical states in the equation.
  - **a.** solid zinc sulfide + oxygen gas  $\longrightarrow$

solid zinc oxide + sulfur dioxide gas

- b. aqueous hydrochloric acid + aqueous barium hydroxide → aqueous barium chloride + water
- **c.** aqueous nitric acid + aqueous calcium hydroxide  $\longrightarrow$  aqueous calcium nitrate + water
- **12.** Translate each of the following chemical equations into a sentence.
  - **a.**  $2\text{ZnS}(s) + 3\text{O}_2(g) \longrightarrow 2\text{ZnO}(s) + 2\text{SO}_2(g)$
  - **b.**  $\operatorname{CaH}_2(s) + 2\operatorname{H}_2\operatorname{O}(l) \longrightarrow \operatorname{Ca(OH)}_2(aq) + 2\operatorname{H}_2(g)$
  - **c.**  $\operatorname{AgNO}_3(aq) + \operatorname{KI}(aq) \longrightarrow \operatorname{AgI}(s) + \operatorname{KNO}_3(aq)$
- 13. Balance each of the following:
  a. H<sub>2</sub> + Cl<sub>2</sub> → HCl
  b. Al + Fe<sub>2</sub>O<sub>3</sub> → Al<sub>2</sub>O<sub>3</sub> + Fe
  - **c.**  $Pb(CH_3COO)_2 + H_2S \longrightarrow PbS + CH_3COOH$
- **14.** Identify and correct each error in the following equations, and then balance each equation.
  - **a.**  $\text{Li} + \text{O}_2 \longrightarrow \text{LiO}_2$
  - **b.**  $H_2 + Cl_2 \longrightarrow H_2Cl_2$
  - c.  $MgCO_3 \longrightarrow MgO_2 + CO_2$
  - **d.** NaI +  $\tilde{Cl}_2 \longrightarrow NaCl + I$
- **15.** Write chemical equations for each of the following sentences:
  - **a.** Aluminum reacts with oxygen to produce aluminum oxide.
  - **b.** Phosphoric acid, H<sub>3</sub>PO<sub>4</sub>, is produced through the reaction between tetraphosphorus decoxide and water.
  - **c.** Iron(III) oxide reacts with carbon monoxide to produce iron and carbon dioxide.
- **16.** Carbon tetrachloride is used as an intermediate chemical in the manufacture of other chemicals. It is prepared in liquid form by reacting chlorine gas with methane gas. Hydrogen chloride gas is also formed in this reaction. Write the balanced chemical equation for the production of carbon tetrachloride. (Hint: See Sample Problems C and D.)

#### CHAPTER REVIEW

17. For each of the following synthesis reactions, identify the missing reactant(s) or product(s), and then balance the resulting equation.

a.  $Mg + \longrightarrow MgO$ 

**b.**  $\longrightarrow$  Fe<sub>2</sub>O<sub>3</sub>

c. 
$$\text{Li} + \text{Cl}_2 \longrightarrow$$

**d.** Ca +  $\longrightarrow$  CaI<sub>2</sub>

#### **SECTION 2** Types of Chemical Reactions

#### REVIEWING MAIN IDEAS

- 18. Define and give general equations for the five basic types of chemical reactions.
- **19.** How are most decomposition reactions initiated?
- 20. A substance is decomposed by an electric current. What is the name of this type of reaction?
- 21. a. In what environment do many single-displacement reactions commonly occur?
  - b. In general, how do single-displacement reactions compare with synthesis and decomposition reactions in terms of the amount of energy involved?

#### **PRACTICE PROBLEMS**

- **22.** Complete each of the following synthesis reactions by writing both a word equation and a chemical equation. **a.** sodium + oxygen  $\longrightarrow$  \_\_\_\_\_
  - **b.** magnesium + fluorine  $\longrightarrow$  \_\_\_\_\_
- **23.** Complete and balance the equations for the following decomposition reactions:
  - **a.** HgO  $\xrightarrow{\Delta}$ **b.** H<sub>2</sub>O(*l*)  $\xrightarrow{\text{electricity}}$

  - **c.**  $\operatorname{Ag}_2O \xrightarrow{\Delta}$  electricity
  - d. CuCl<sub>2</sub> -
- **24.** Complete and balance the equations for the following single-displacement reactions:
  - **a.**  $Zn + Pb(NO_3)_2 \longrightarrow \_$
  - **b.** Al + Hg(CH<sub>3</sub>COO)<sub>2</sub>  $\longrightarrow$  \_\_\_\_\_
  - **c.** Al + NiSO<sub>4</sub>  $\longrightarrow$  \_\_\_\_\_
  - **d.** Na +  $H_2O \longrightarrow$
- 25. Complete and balance the equations for the following double-displacement reactions:

**a.** 
$$\operatorname{AgNO}_3(aq) + \operatorname{NaCl}(aq) \longrightarrow$$

**b.** 
$$Mg(NO_3)_2(aq) + KOH(aq) \longrightarrow$$

**c.**  $\text{LiOH}(aq) + \text{Fe}(\text{NO}_3)_3(aq) \longrightarrow$ 

**26.** Complete and balance the equations for the following combustion reactions:

**a.** 
$$CH_4 + O_2 \longrightarrow$$

**b.** 
$$C_3H_6^4 + O_2^2 \longrightarrow \_$$

- **c.**  $C_3H_6 + O_2 \longrightarrow$ **c.**  $C_5H_{12} + O_2 \longrightarrow$
- 27. Write and balance each of the following equations, and then identify each by type.
  - **a.** hydrogen + iodine  $\longrightarrow$  hydrogen iodide
  - **b.** lithium + hydrochloric acid  $\longrightarrow$ 
    - lithium chloride + hydrogen
  - c. sodium carbonate
    - sodium oxide + carbon dioxide
  - **d.** mercury(II) oxide  $\longrightarrow$  mercury + oxygen
  - e. magnesium hydroxide -

magnesium oxide + water

- 28. Identify the compound that could undergo decomposition to produce the following products, and then balance the final equation.
  - a. magnesium oxide and water
  - **b.** lead(II) oxide and water
  - c. lithium chloride and oxygen
  - **d.** barium chloride and oxygen
  - e. nickel chloride and oxygen
- 29. In each of the following combustion reactions, identify the missing reactant(s), product(s), or both, and then balance the resulting equation.

**a.** 
$$C_3H_8 + - + H_2O$$

- **b.**  $\_$  + 80<sub>2</sub>  $\rightarrow$  5CO<sub>2</sub> + 6H<sub>2</sub>O **c.** C<sub>2</sub>H<sub>5</sub>OH +  $\_$  +  $\_$  +  $\_$
- **30.** Complete and balance the equations for the following reactions, and then identify each by type.
  - **a.** zinc + sulfur  $\rightarrow$  \_
  - **b.** silver nitrate + potassium iodide  $\rightarrow$  \_
  - **c.** toluene,  $C_7H_8 + oxygen \longrightarrow$
  - **d.** nonane,  $C_9H_{20}$  + oxygen  $\longrightarrow$  \_\_\_\_\_

#### **SECTION 3** Activity Series of the Elements

#### REVIEWING MAIN IDEAS

- 31. a. What is meant by the *activity* of an element?
  - b. How does this description differ for metals and nonmetals?

- **32. a.** What is an activity series of elements?
  - **b.** What is the basis for the ordering of the elements in the activity series?
- **33. a.** What chemical principle is the basis for the activity series of metals?
  - **b.** What is the significance of the distance between two metals in the activity series?

#### **PRACTICE PROBLEMS**

- **34.** Based on the activity series of metals and halogens, in **Figure 3.1**, which element within each pair is more likely to replace the other in a compound?
  - a. K and Nab. Al and Nic. Au and Agf. Cl and I
  - **c.** Bi and Cr **g.** Fe and Sr
  - **d.** Cl and F **h.** I and F
- **35.** Using the activity series in **Figure 3.1**, predict whether each of the possible reactions listed below will occur. For the reactions that will occur, write the products and balance the equation.
  - **a.** Ni(s) + CuCl<sub>2</sub>(aq)  $\longrightarrow$  \_\_\_\_\_
  - **b.**  $\operatorname{Zn}(s) + \operatorname{Pb}(\operatorname{NO}_3)_2(aq) \longrightarrow$
  - **c.**  $\operatorname{Cl}_2(g) + \operatorname{KI}(aq) \longrightarrow$
  - **d.**  $\operatorname{Cu}(s) + \operatorname{FeSO}_4(aq) \longrightarrow \_$
  - **e.**  $Ba(s) + H_2O(l) \longrightarrow$
- **36.** Use the activity series in **Figure 3.1** to predict whether each of the following synthesis reactions will occur, and write the chemical equations for those predicted to occur.
  - **a.**  $Ca(s) + O_2(g) \longrightarrow$
  - **b.** Ni(s) +  $O_2(g) \longrightarrow$
  - **c.**  $\operatorname{Au}(s) + \operatorname{O}_2(g) \longrightarrow$

#### **Mixed Review**

REVIEWING MAIN IDEAS

**37.** Ammonia reacts with oxygen to yield nitrogen and water.

 $4NH_3(g) + 3O_2(g) \longrightarrow 2N_2(g) + 6H_2O(l)$ 

Given this chemical equation, as well as the number of moles of the reactant or product indicated below, determine the number of moles of all remaining reactants and products.

**a.**  $3.0 \mod O_2$ **b.**  $8.0 \mod NH_3$ **c.**  $1.0 \mod N_2$ **d.**  $0.40 \mod H_2O$ 

- **38.** Complete the following synthesis reactions by writing both the word and chemical equation for each:
  - **a.** potassium + chlorine  $\longrightarrow$  \_\_\_\_\_
  - **b.** hydrogen + iodine  $\longrightarrow$  \_\_\_\_\_
  - **c.** magnesium + oxygen  $\longrightarrow$  \_\_\_\_\_
- **39.** Use the activity series in **Figure 3.1** to predict which metal—Sn, Mn, or Pt—would be the best choice as a container for an acid.
- **40.** Aqueous sodium hydroxide is produced commercially by the electrolysis of aqueous sodium chloride. Hydrogen and chlorine gases are also produced. Write the balanced chemical equation for the production of sodium hydroxide. Include the physical states of the reactants and products.
- **41.** Balance each of the following:
  - **a.**  $Ca(OH)_2 + (NH_4)_2SO_4 \longrightarrow CaSO_4 + NH_3 + H_2O$  **b.**  $C_2H_6 + O_2 \longrightarrow CO_2 + H_2O$  **c.**  $Cu_2S + O_2 \longrightarrow Cu_2O + SO_2$ **d.**  $Al + H_2SO_4 \longrightarrow Al_2(SO_4)_3 + H_2$
- **42.** Use the activity series in **Figure 3.1** to predict whether each of the following reactions will occur, and write the balanced chemical equations for those predicted to occur.
  - **a.**  $Al(s) + O_2(g) \longrightarrow$
  - **b.**  $Pb(s) + ZnCl_2(s) \longrightarrow$
- **43.** Complete and balance the equations for the following reactions, and identify the type of reaction that each equation represents.
  - **a.**  $(NH_4)_2S(aq) + ZnCl_2(aq) \longrightarrow \_\_\_+ ZnS(s)$  **b.**  $Al(s) + Pb(NO_3)_2(aq) \longrightarrow \_\_\_$  **c.**  $Ba(s) + H_2O(l) \longrightarrow \_\_\_$  **d.**  $Cl_2(g) + KBr(aq) \longrightarrow$  **e.**  $NH_3(g) + O_2(g) \xrightarrow{Pt} NO(g) + H_2O(l)$ **f.**  $H_2O(l) \longrightarrow H_2(g) + O_2(g)$
- **44.** Write and balance each of the following equations, and then identify each by type.
  - **a.** copper + chlorine  $\longrightarrow$  copper(II) chloride
  - **b.** calcium chlorate  $\longrightarrow$ 
    - calcium chloride + oxygen
  - **c.** lithium + water  $\longrightarrow$

lithium hydroxide + hydrogen

**d.** lead(II) carbonate  $\longrightarrow$ lead(II) oxide + carbon dioxide

- **45.** How many moles of HCl can be made from 6.15 mol H<sub>2</sub> and an excess of Cl<sub>2</sub>?
- 46. What product is missing in the following equation?

 $MgO + 2HCl \longrightarrow MgCl_2 +$ 

47. Balance the following equations: a.  $Pb(NO_3)_2(aq) + NaOH(aq) \longrightarrow$   $Pb(OH)_2(s) + NaNO_3(aq)$ b.  $C_{12}H_{22}O_{11}(l) + O_2(g) \longrightarrow CO_2(g) + H_2O(l)$ c.  $Al(OH)_3(s) + H_2SO_4(aq) \longrightarrow$  $Al_2(SO_4)_3(aq) + H_2O(l)$ 

#### **CRITICAL THINKING**

- **48. Inferring Relationships** Activity series are prepared by comparing single-displacement reactions between metals. Based on observations, the metals can be ranked by their ability to react. However, reactivity can be explained by the ease with which atoms of metals lose electrons. Using information from the activity series, identify the locations in the periodic table of the most reactive metals and the least reactive metals. Using your knowledge of electron configurations and periodic trends, infer possible explanations for the metals' reactivity and position in the periodic table.
- **49. Analyzing Results** Formulate an activity series for the hypothetical elements A, J, Q, and Z by using the following reaction information:

$$\begin{array}{c} A + ZX \longrightarrow AX + Z \\ J + ZX \longrightarrow no \ reaction \\ Q + AX \longrightarrow QX + A \end{array}$$

#### **USING THE HANDBOOK**

- **50.** Find the common-reactions section for Group 1 metals in the *Elements Handbook* in Appendix A. Use this information to answer the following:
  - **a.** Write a balanced chemical equation for the formation of rubidium hydroxide from rubidum oxide.
  - **b.** Write a balanced chemical equation for the formation of cesium iodide.
  - **c.** Classify the reactions you wrote in (a) and (b).
  - **d.** Write word equations for the reactions you wrote in (a) and (b).

- **51.** Find the common-reactions section for Group 13 in the *Elements Handbook* (Appendix A). Use this information to answer the following:
  - **a.** Write a balanced chemical equation for the formation of gallium bromide prepared from hydrobromic acid.
  - **b.** Write a balanced chemical equation for the formation of gallium oxide.
  - **c.** Classify the reactions you wrote in (a) and (b).
  - **d.** Write word equations for the reactions you wrote in (a) and (b).

#### **RESEARCH AND WRITING**

- **52.** Trace the evolution of municipal water fluoridation. What advantages and disadvantages are associated with this practice?
- **53.** Research how a soda-acid fire extinguisher works, and write the chemical equation for the reaction. Check your house and other structures for different types of fire extinguishers, and ask your local fire department to verify the effectiveness of each type of extinguisher.

#### **ALTERNATIVE ASSESSMENT**

54. Performance Assessment For one day, record situations that show evidence of a chemical change. Identify the reactants and the products, and determine whether there is proof of a chemical reaction. Classify each of the chemical reactions according to the common reaction types discussed in the chapter.

# **Standards-Based Assessment**

Answer the following items on a separate piece of paper.

#### **MULTIPLE CHOICE**

- **1.** According to the law of conservation of mass, the total mass of the reacting substances is
  - **A.** always more than the total mass of the products.
  - **B.** always less than the total mass of the products.
  - **C.** sometimes more and sometimes less than the total mass of the products.
  - **D.** always equal to the total mass of the products.
- 2. To balance a chemical equation, you may adjust the
  - **A.** coefficients.
  - **B.** subscripts.
  - **C.** formulas of the products.
  - **D.** either the coefficients or the subscripts.
- **3.** Which is the correct chemical equation for the following formula equation:  $(NH_4)_2S \longrightarrow NH_3 + H_2S$ ?
  - **A.**  $2(NH_4)_2S \longrightarrow 2NH_3 + H_2S_2$
  - **B.**  $2(NH_4)_2S \longrightarrow 2NH_3 + H_2S$
  - **C.**  $(NH_4)_2 S \longrightarrow 2NH_3 + H_2 S$
  - **D.** None of the above
- **4.** Select the missing reactant(s) for the doubledisplacement reaction that produces  $PF_5$ and  $AsCl_3$ .
  - **A.**  $PCl_5$  and  $AsF_3$
  - **B.**  $PCl_3$  and  $AsF_5$
  - **C.**  $PCl_3$  and  $AsF_3$
  - **D.** None of the above
- **5.** Select the missing reactant for the following combustion reaction:  $2 \_\_\_\_ + 15O_2 \Longrightarrow$  $14CO_2 + 6H_2O.$ **A.**  $C_{14}H_{12}$ **B.**  $C_{14}H_{12}O_4$ **C.**  $C_7H_6$ 
  - **D.**  $C_7H_6O_2$
- **6.** A mixture consists of Ag, Pb, and Fe metals. Which of these metals will react with ZnCl<sub>2</sub>?
  - **A.** Ag(s)
  - **B.** Pb(s)
  - **C.** Fe(s)
  - **D.** None of these metals

- 7. Which of the following statements is true about the reaction  $2F_2 + 2H_2O \longrightarrow 4HF + O_2$ ?
  - **A.** Two grams of  $O_2$  are produced when 2 g  $F_2$  reacts with 2 g  $H_2O$ .
  - **B.** Two moles of HF are produced when 1 mol  $F_2$  reacts with 1 mol  $H_2O$ .
  - **C.** For every 2 mol O<sub>2</sub> produced, 6 mol HF are produced.
  - **D.** For every 1 mol  $H_2O$  that reacts, 2 mol  $O_2$  are produced.

#### SHORT ANSWER

- **8.** Determine the products and write a balanced equation for the reaction of solid magnesium and water.
- **9.** A precipitation of iron(III) hydroxide is produced by reacting an aqueous solution of iron(III) chloride with an aqueous solution of sodium hydroxide. Write a balanced chemical equation.

#### EXTENDED RESPONSE

**10.** List the hypothetical metals A, E, M, and R in increasing order of reactivity by using the reaction data in the table below. The reaction of interest is of the form  $C + ZX \longrightarrow CX + Z$ . Explain your reasoning.

	AX	EX	MX	RX
A		no reaction	reaction	no reaction
E	reaction		reaction	reaction
Μ	no reaction	no reaction		no reaction
R	reaction	no reaction	reaction	

**11.** Calcium hypochlorite, Ca(OCl)<sub>2</sub>, is a bleaching agent produced from sodium hydroxide, calcium hydroxide, and chlorine. Sodium chloride and water are also produced in the reaction. Write the balanced chemical equation. If 2 mol NaOH react, how many moles of calcium hypochlorite can be produced?

#### Test Tip

Focus on one question at a time unless you are asked to refer to previous answers.
